

Annual Weather Summary over Thailand in 2013

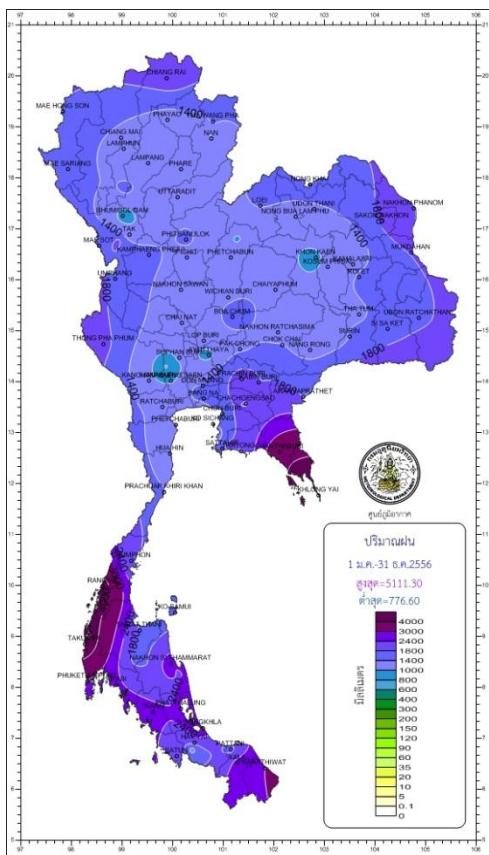

The year 2013 started to be warmer than usual. Monthly mean air temperatures were above normal from January to November, while February and November mean temperatures in upper Thailand were more than 1°C above normal. In addition, a heat low pressure cell affected upper Thailand during March to April, and caused to break previous records with daily maximum temperatures exceeding 40°C in some locations. However, this warm anomaly was inversely to the cooler weather in December with monthly mean temperature 1.4 °C below normal. Rainy season began mid-May as usual. Moreover, Thailand received unseasonal rainfall in January and occasional flooding occurred in some places from May to July. During September, one tropical depression hit Thailand on September 19 and active monsoon trough lay across upper Thailand almost of the month. These brought torrential rain that caused severe flooding mainly in the lower northeastern, central and eastern parts. In early October, upper Thailand was hit by tropical storm which downgraded from Typhoon Wutip (1321), with heavy rain occurring in some areas. Moreover, low pressure cells that weakened from tropical storms and westerly trough brought unseasonal rainfall to Thailand November and mid-December respectively. The accumulated rainfall over 2013 was about 11 % above normal. More details on the weather are at Thailand's monthly weather summary website.
